Multiple Environmental Effects

376. **Agri-Environmental Policy at the Crossroads: Guideposts on a Changing Landscape.**

Descriptors: environmental benefits/ conservation programs/ evaluation

Abstract: Discussed development and implementation of a farmer payment system based on a comprehensive measurement of environmental benefits and tradeoffs from agricultural practices endorsed under numerous USDA conservation programs.

377. **Agricultural Conservation: State Advisory Committees' Views on How USDA Programs Could Better Address Environmental Concerns.**

Notes: PB-2002104592XSP; Report to the Congress.

Descriptors: Program participation/ Surveys/ Payments/ Funding/ Benefits/ Congressional reports/ Conservation programs/ Agricultural conservation/ Environmental concerns/ State technical committees/ State advisory committees/ United States Department of Agriculture/ Agriculture and food/ Environmental pollution and control

Abstract: The future of USDA conservation programs has been the subject of extensive debate within the environmental and agricultural communities and in the Congress. This debate has centered on increasing the environmental and natural resource benefits resulting from the programs by allocating more funding to them, modifying them, or creating new programs. Pursuant to this debate, the omnibus farm bill is expected to become law in 2002. In this context, you asked us to obtain the views of members of state technical committees on (1) the effectiveness of USDA's conservation efforts in addressing environmental concerns related to agriculture and (2) any program elements that hinder the achievement of environmental objectives related to agriculture, as well as program characteristics that current or new programs might include to better meet these objectives. Also, you asked us to provide information on program participation and the extent to which applications for program participation exceed program funding as well as the geographic distribution of payments for each program. This information is provided in appendices I and II, respectively. To provide information on the views of members of state technical committees for our first two objectives, we mailed a questionnaire to all NRCS state conservationists and a sample of 1,470 committee members and received 996 responses. We drew the sample from the 2,124 state technical committee members in all 50 states and two territories. The sample was stratified by geographic region and the organizations the members represent, and the overall survey results are generalizable to the entire population. All percentage estimates from the survey have sampling errors of plus or minus 7 percentage points or less, unless otherwise noted. The survey solicited views on the effectiveness of CRP General Enrollment, CRP Continuous Enrollment, CREP, Wetlands Reserve Program, Environmental Quality Incentives Program, Wildlife Habitat Incentives Program, and Farmland Protection Program. For CREP and the Farmland Protection Program, which are relatively new programs, our results include only those states where the programs were implemented at the time of our survey.

Abstract: Farmers, ranchers, and private forest landowners own and manage more than two-thirds of the continental United States 1.9 billion acres and thus are the primary stewards of our soil, water, and wildlife habitat. Because of this important responsibility, how private land is used is increasingly being recognized as vital to the protection of the nation's environment and natural resources. For example, state water quality agencies report that agricultural production is a leading contributor to impaired water quality; similarly, habitat loss associated with agriculture has been a factor in the declining populations of many wildlife species, including many threatened or endangered native species. In recognition of the critical role played by private landowners, the Congress directed the U.S. Department of Agriculture (USDA) to implement the numerous programs aimed at improving the stewardship practices on these lands. USDA currently has over 70 million acres of privately owned land enrolled in programs that offer landowners financial incentives to implement conservation practices.
practices to protect or improve soil and water quality and wildlife habitat. USDA's conservation efforts are intended to address specific environmental concerns, target funding toward state and local environmental priority areas, and include partnerships with state or local entities to leverage limited funding. USDA's Conservation Reserve Program (CRP), the federal government's largest single conservation program, has an enrollment of almost 34 million acres and makes annual payments of about $1.5 billion on these acres.

Abstract: Between 1987 and 1991, 1892 prairie potholes were restored in northern Iowa, southern Minnesota, and southeastern South Dakota by state and federal agencies, most as part of the Conservation Reserve Program. The total area covered by these restored wetlands is approximately 2714 ha. Most restorations are small (less than 4 ha)
Environmental Effects of USDA Conservation Programs: Multiple Environmental Effects

Wetlands with a seasonal hydrologic regime. Wetlands with an ephemeral/temporary water regime are under-represented compared to their pre-drainage extent. Information on basin morphometry, hydrology, and vegetation-zone development was collected on 62 wetlands restored in 1988. Earthen dams are installed on most (73%) restorations in the region, increasing the full pool volume but not the mean depth of the basin. Overall, restored wetlands have basin morphometries that are comparable to those of similarly sized natural wetlands. About 60% of the basins had their predicted hydrology or held water longer than predicted. Nevertheless, about 20% of the projects that we examined were hydrologic failures and either never flooded or had significant structural problems. Most restored wetlands had developed emergent and submersed aquatic vegetation zones, but only a few had developed wet prairie and sedge meadow vegetation zones. © Cambridge Scientific Abstracts (CSA)

387. Conservation Reserve Program: Alternatives are available for managing environmentally sensitive cropland.
General Accounting Office
Notes: GAO/RCED-95-42
Descriptors: cultivated lands/ land management/ agriculture/ land use/ water quality/ Watershed protection
Abstract: If not properly managed, agricultural production on the nation's 382 million cropland acres can adversely affect the quality of water and air, the productivity of soil, and the availability of wildlife habitat. In an effort to reduce these effects by temporarily removing highly erodible cropland from production, the Congress enacted the Conservation Reserve Program (CRP) in 1985. The CRP was also designed to reduce surplus crop production and support farm income. Under the CRP, the U.S. Department of Agriculture (USDA) contracted with farmers to take 36.4 million acres out of production for 10 years in return for rental and cost-share payments of almost $20 billion through the year 2002. These contracts will begin to expire in 1995, with the contracts for the majority of acres-22 million-expiring in 1996 and 1997.

Descriptors: Farms/ Income/ Food/ Prices/ Soil erosion/ Water quality/ Evaluation/ Conservation/ Agricultural economics/ Natural resources management/ Costs/ Programs/ Environment management/ Agriculture and food/ Agricultural economics/ Natural resources and earth sciences/ Natural resource management/ Soil sciences
Abstract: The Conservation Reserve Program (CRP) will boost net farm income and improve environmental quality substantially over the life of the program (1986-99). These gains will come at the cost of somewhat higher food prices and Government administrative expenses, and potential downturns in farm input industries and other local economic activity tied to farming where enrollment is heavy. Net economic benefits of the program range between $3.4 billion and $11.0 billion in present value, according to estimates derived in the report. The report also looks behind the bottom-line estimate to determine how well the CRP does in reaching each of its multiple goals, which are to reduce soil erosion, protect the Nation's long-term capability to produce food and fiber, reduce sedimentation, improve water quality, create better habitat for fish and wildlife, curb production of surplus commodities, and provide income support to farmers.

Abstract: The Environmental Benefits Index (EBI) is used to evaluate and rank land offered for enrollment in the Conservation Reserve Program (CRP) during a general sign-up. Scores are based on the expected environmental benefits to soil resources, water quality, wildlife habitat, and other resource concerns during the time the land is to be enrolled in the program. Each offer submitted is assigned a point score based on its relative environmental benefits. Each offer is compared nationally with all other offers at the end of the sign-up. Offers are determined acceptable or rejected based on the ranking results.

Abstract: After Conservation Reserve Program (CRP) contracts expire, annual rental payments made by USDA to CRP participants will end and producers will decide the next use of their land. Most CRP acres will either be planted to crops, depending largely on commodity market conditions, placed in annual acreage set-asides, kept in grass for livestock production, or left idle. Land first placed in the CRP will be available for crop production or other uses starting in late 1995. The expiration of CRP contracts raises concerns over the extent of conservation, wildlife and environmental reversals that will occur, particularly if commodity markets are favorable in 1996 and 1997. While the conservation compliance provision of farm legislation will not prevent much CRP land from returning to production, it will moderate increases in soil erosion and onsite productivity losses on most CRP land that is recropped. However, the effectiveness of conservation compliance in protecting water quality is unclear, and it will do little to maintain wildlife habitat benefits currently provided by CRP. Keeping all CRP

398. Conversion of Conservation Reserve Program (CRP) grassland for dryland crops in a semiarid region.
Unger, P. W.
NAL Call #: 4-AM34P; ISSN: 0002-1962 [AGJOAT]
Descriptors: sorghum bicolor/ triticium aestivum/ grasslands/ agricultural land/ tillage/ conservation tillage/ no-tillage/ plowing/ prescribed burning/ vegetation/ ammonium nitrate/ application rates/ soil water content/ drought/ crop yield/ water stress/ land banks/ Texas
Abstract: Information was needed regarding practices suitable for returning grassland to cropland when Conservation Reserve Program (CRP) contracts expired. A study on Pullman soil (Torriertic Paleustoll) involved seven tillage treatments (no-tillage and reduced, sweep, disk, moldboard plus disk, burn-sweep, and burn-disk tillage) with vegetation retained and the five non-burn tillage treatments with vegetation removed before treatment. Fertilizer (NH(4)NO(3)) was applied at 0, 34, and 67 kg N ha(-1) in 1995 and at 0, 67, and 134 kg N ha(-1) in 1996 and 1997. Initial soil water contents were low, and soil never was filled with water at planting time. Sorghum [Sorghum bicolor (L.) Moench] yielded < or = 720 kg ha(-1) in 1995, and the 1995-1996 wheat (Triticum aestivum L.) crop failed. Sorghum was not planted in 1996 because of a drought. Sorghum yielded 2260 to 4700 kg ha(-1) in 1997. Wheat yielded 1410 to 1980 kg ha(-1) in 1996-1997. Vegetation retention or removal affected yields slightly. Fertilization affected sorghum yields slightly and increased wheat yields. Vegetation control was difficult with no-tillage. Disk tillage to dislodge grass, followed by reduced or no-tillage, appears best for converting CRP grassland to cropland in this semiarid region. Because of low initial soil water contents, a 90-d period is inadequate for obtaining adequate soil water storage unless precipitation is much above normal. Forgoing planting a crop soon after killing the vegetation when precipitation is low would provide more time for storing soil water and increase the potential for obtaining favorable yields. 399. Costs and Benefits of the Conservation Reserve Program.
Young, C. E. and Osborn, C. T.
NAL Call #: 56.8 J822 [JSWCA3]
Descriptors: Cost benefit analysis/ Cropland/ Economic aspects/ Erosion control/ Land use/ Soil conservation/ Administration/ Administrative agencies/ Conservation Reserve Program/ Cultivated lands/ Federal jurisdiction/ Soil erosion/ Watershed protection
Abstract: The economic efficiency of the Conservation Reserve Program (CRP) was evaluated. The CRP is a voluntary, long-term cropland retirement program with a targeted enrollment of 40-45 million acres. In exchange for retiring cropland with highly erodible soils or other environmentally sensitive land for 10 years, the U.S. Department of Agriculture pays CRP participants (farm owners or operators) an annual per-acre rent and one-half the cost of establishing a permanent land cover. The CRP’s primary goal is to reduce soil erosion on highly erodible cropland. Primary effects of the CRP are the following: changes in farm income; timber production; consumer costs; soil productivity; surface water quality, including filter strips; wildlife habitat; wind erosion; administrative costs; cost-sharing of vegetative cover; and technical assistance costs. CRP impacts were uniformly compared to a baseline situation characterized by the absence of CRP. Based upon estimates of the primary effects, the present value of net benefits for a 45 million acre CRP could range from $3.4 to $11.0 billion. (MacKeen-PTT) © Cambridge Scientific Abstracts (CSA)

Abstract: The Conservation Reserve Program was initiated in 1985 to reduce soil loss on highly erodible agricultural land. This stated objective of the program has been quite successful. However, there are other unintentional yet significant ecological benefits to the program that merit evaluation. These benefits include the reversal of landscape fragmentation, maintenance of regional biodiversity, creation of wildlife habitat, and favorable changes in regional carbon flux. These and other benefits should be used by policy makers and federal officials to maintain the program even after enrollment expectations have been achieved.
© Cambridge Scientific Abstracts (CSA)
agriculture, the Conservation Reserve Program (CRP) has broadened its initial focus on reductions in soil erosion to consider other landscape factors that may also be beneficial. For example, preserving habitats can help protect wildlife, thus leading to more nature-viewing opportunities. This report demonstrates how nonmarket valuation models can be used in targeting conservation programs such as the CRP.

406. Effects of soil and agricultural chemicals management on farm returns and ground water quality.

*Descriptors:* Environment management/ Agricultural land/ Soil erosion/ Environmental monitoring/ Conservation/ Indicators/ Agriculture/ Management/ Environmental & Natural Resource Development
*Abstract:* Environmental indicators can be used to target public programs to provide a variety of benefits. Social scientists, physical scientists, and politicians have roles in developing indicators that reflect the demands of diverse interest groups. We review the US Department of Agriculture’s Conservation Reserve Program (CRP), the largest agricultural conservation program of the United States, to determine how a set of environmental indicators were developed and used, and assess results of their application. The use of such indicators has helped the CRP increase and broaden the program’s environmental benefits beyond erosion reduction, which was the primary focus of early program efforts, to meet other demands. This case study provides an example about how integration and assessment for the purpose of managing public resources requires more than natural science disciplines. Social science can help explain how public values influence what information is collected and how it is interpreted. Examples are given to show how the indices used for the CRP integrated science, politics and social values. In the end, the environmental benefits index (EBI) used to target US$ 20 billion of CRP funds reflects compromises made between science and policy considerations. It is our intention that studying this index will yield ideas and understanding from the natural science community that develops ecosystem indices about how to better plug in to programs in the future.

412. Evaluating the sustainability of alternative farming systems: A case study.
Ikerd, J.; Devino, G.; and Traiyongwanich, S.
NAL Call #: S605.5.A43; ISSN: 0889-1893 [AJAAEZ]
Abstract: The sustainability of farming systems must be assessed by their potential environmental, economic, and social performance. We present a case study to illustrate an assessment of relative sustainability that uses all three performance criteria. We developed two scenarios for farmland currently enrolled in the Conservation Reserve Program (CRP) in Putnam County, Missouri: a conventional scenario reflecting farming practices typical of northern Missouri, and an alternative that we hypothesize to be more environmentally sound. We used selected economic and social indicators to assess whether the latter would be at least as economically viable and socially responsible as the conventional system. Estimated direct farm income was $3.4 million for the alternative and $2.4 million for the conventional scenario. The alternative system applies more labor and management to a given land resource and may support more farming families. Estimated total community economic impacts were 25% greater for the alternative than the conventional farming scenario. CRP land, therefore, could be resumed to production in a way that could significantly enhance local economic and social benefits while retaining many of the CRP's environmental benefits.

413. Expanding the conservation reserve to achieve multiple environmental goals.
Ogg, C. W.; Hostetter, J. E.; and Lee, D. J.
NAL Call #: 56.8-J822; ISSN: 0022-4561
Descriptors: conservation/soils/environmental management/ecology/Food Security Act 1985/Standards, laws, regulations and policy
Abstract: The 1985 Food Security Act (P.L. 99-198) authorizes the largest Conservation Reserve Program in history. Although this act emphasizes the need to alleviate huge surpluses of federally stored grain and reduce financial distress among farmers, it designates only certain highly erodible acres or other acres that "pose an off-farm environmental threat" for CRP eligibility. The program has the potential to both conserve soil and reduce crop surpluses by idling within the next five years as many acres as last year's unusually large farm program acreage set-aside.

(Nov. 1996)  
NAL Call #: S671.A66; ISSN: 0883-8542  
Abstract: Grazing and haying effects on runoff and erosion from a former Conservation Reserve Program (CRP) site near Streeter, North Dakota, were determined. Treatments included undisturbed CRP, twice-over rotational grazing, season-long haying, and burning. Runoff and erosion were measured from simulated rainfall which was applied to 3.7 X 10.7 m (12.0 X 35.1 ft) plots. Following an initial stabilization period, no significant difference in runoff or erosion was found between the season-long grazing and burned treatments. Use of the CRP site for grazing or haying resulted in a significant increase in runoff compared to leaving the area in an undisturbed condition. Similar amounts of erosion were measured from the twice-over rotational grazing, season-long grazing, and hayed treatments. If adequate canopy and basal cover is maintained, use of this CRP site for grazing or haying would not be expected to result in excessive erosion.

Licht, Daniel S.  
Wild Earth 4 (2): 47-53. (1994); ISSN: 1055-1166  
Abstract: The author discusses the Conservation Reserve Program (CRP) in the United States and its effect on Great Plains wildlife and ecosystems. Although a large number of acres are temporarily taken out of agricultural use under the CRP program, the individual tracts are small. Very often, farmers plant exotic grasses on the CRP tracts instead of native ones that would support native wildlife species. 425. Haying, tillage, and nitrogen fertilization influences on infiltration rates at a Conservation Reserve Program site.  
Wienhold, B. J. and Tanaka, D. L.  
NAL Call #: 56.9-So3; ISSN: 0361-5995 [SSSJD4]  
Descriptors: mollisols/ entisols/ infiltration/ grassland soils/ land use/ conversion/ harvesting/ tillage/ no-tillage/ minimum tillage/ nitrogen fertilizers/ North Dakota  
Abstract: Effect of haying (hayed or not hayed prior to tillage), tillage (no-tillage, minimum tillage, or conventional tillage), and N fertilization (0 or 67 kg ha(-1)) on surface infiltration rates, Q(h), was evaluated for Conservation Research Program (CRP) site conversion. Soils included Amor loam (fine-loamy, mixed, superactive, frigid Typic Haplustoll) and Cabba silt loam (loamy, mixed, superactive, calcareous, frigid, shallow Typic Ustorthent). In reference plots Q(h) increased from 1995 to 1997 (27.2 +/- 3.2 vs. 36.4 +/- 2.9 mm h(-1) at 50-mm tension, 10.9 +/- 1.4 vs. 20.6 +/- 1.4 mm h(-1) at 100-mm tension, and 4.1 +/- 0.6 vs. 10.9 +/- 1.1 mm h(-1) at 150 mm-tension) under permanent vegetation. Plots hayed prior to tillage exhibited higher Q(h) when no fertilizer was applied than plots hayed and fertilized or not hayed (31.9 +/- 2.9 vs. 23.3 +/- 1.3 mm h(-1) at 50-mm tension and 18.1 +/- 1.3 vs. 13.5 +/- 0.6 mm h(-1) at 100-mm tension). As tillage intensity increased, Q(h) at 50-mm tension increased (20.1 +/- 2.6 mm h(-1) under no-tillage, 25.5 +/- 1.6 mm h(-1) under minimum tillage, and 30.1 +/- 2.0 mm h(-1) under conventional tillage). Q(h) did not change from 1995 to 1997 in cropped plots.

*Abstract:* The Conservation Reserve Program (CRP) technical rept. 158; 142 p. (1988) is a multi-year, the multi-objective program of the Secretary of Agriculture has considerable discretion in implementing the program. The report analyzes the effects of various eligibility, pooling, and bid selection criteria on the performance of the Conservation Reserve. The program can be implemented to favor erosion reduction, supply control, or budget reduction to varying degrees. Furthermore, the operation and performance of the CRP are closely linked with other conservation and commodity program provisions of the 1985 Food Security Act.

*Abstract:* Benefits would be mixed if the Conservation Reserve Program (CRP) were expanded to include irrigated land, highly erodible land, and land with wetness problems, which contribute to environmental problems. The report examines the following options for implementing environmental provisions of the CRP: Irrigated land. Enrollment costs for the acreage are high since irrigation is profitable in many areas. Net environmental benefits would not likely increase. Erodible land in watersheds with pollution problems. Water quality could benefit considerably by targeting selected watersheds. Targeting modest acreages of buffer strips near streams would increase benefits even more. Wildlife habitat would improve by restoring up to 6 million acres to wetlands.

Abstract: The report identifies technical assistance and financial incentives to accomplish different resource conservation objectives based on analysis of possible conservation initiatives. The initiatives include reducing erosion on all cropland, implementing a cropland stewardship proposal, accomplishing two million miles of buffers for the nations waterways, enrolling 250,000 additional acres per year in the Wetlands Reserve Program, investing $65 million per year in the Farmland Protection Program and expanding the Conservation Reserve Program to 45 million acres. Overall results indicate that there are significant opportunities to improve soil, water and other environmental conditions into the future.

Abstract: The Conservation Reserve Program (CRP) may generate $6-14 billion (present value) in benefits to natural resources if 45 million acres of highly
erodible or environmentally sensitive cropland are removed from agricultural production by 1990. Protecting the soil by retiring and planting permanent grasses and trees on such land for 10 years will improve soil productivity, water quality, air quality, wildlife habitat, and groundwater supply. But the magnitude and distribution of benefits can be altered by changing the emphasis of the program. The report estimates how retiring cropland benefits natural resources under three scenarios of CRP enrollment.

Watershed protection
Abstract: In the early 1980s, articles in this Journal made ambitious claims regarding long term cropland diversion. They said that the U.S. could dramatically reduce soil erosion while avoiding annual, paid diversion programs, which cost much more. The Conservation Reserve Program (CRP) now plays a central role in farm bill debates largely because it is delivering on those promises, while meeting wildlife needs, as well. Success opens up new opportunities to design effective programs based, again, on good analysis, but focusing more on wildlife and water quality benefits from crop diversions and on supporting resource management on land remaining in crop production.

**Abstract:** This study was conducted to measure runoff, erosion, and soil quality characteristics of a site in southwestern Oklahoma the first year following conversion from the Conservation Reserve Program (CRP). Treatments included undisturbed CRP, Old World bluestem (Bothriochlora ischaemum L.), no-till wheat (Triticum aestivum L.) and conservation-till wheat. Significant differences in surface cover were found between each of the experimental treatments, with values ranging from 100% on the undisturbed CRP site to 42% for the conservation-till treatment. No significant difference in runoff was found among the various experimental treatments. The Old World bluestem and winter wheat treatments had only minimal erosion during the first year following conversion from the CRP. Production of Old World bluestem maintained levels of soil quality similar to those of the undisturbed CRP. Conversion of this CRP area to winter wheat production significantly reduced biological nutrient reserves, suggesting a degradation of soil quality. If this trend continues, long term productivity and the quality of air and water resources at this site could be affected. This citation is from AGRICOLA.

Bogovich, W. M.

One-sixth of all abandoned coal-mine land in the United States is in the twelve southwestern counties of Pennsylvania. The Surface Mining Control Act of 1977 established several programs to reclaim abandoned coal mine land, one of which is the Rural Abandoned Mine Program. Sites reclaimed to date have all been Priority I sites, defined as those which present an imminent danger to life and property. 136 sites totalling 1137 acres (460 ha) have been reclaimed in the twelve counties over the last 12 years. One of the biggest problems associated with black gob piles is their potential toxicity to vegetation. A soil covering has been used on two of the 136 sites. Black locust and arnot bristly locust have been propagated on sites from seed during the vegetation phase of reclamation. During construction, both temporary and permanent measures for the control of erosion and sedimentation are installed, including: straw-bale barriers, filter-fabric fence, sediment basins and rock filter dams. Before reconstruction, many of the sites had high rates of sediment leaving the site. Surface-water control practices are used to stabilize the soil material and reduce the amount of gully erosion; examples are diversions, vegetated waterways, and rock-lined waterways. Mine openings and air shafts may discharge water and poorly-oxygenated air, and 183 openings have been closed to prevent access. Wetlands have been constructed on 11 sites to mitigate acid mine drainage. The average total cost of reclamation is approximately 9500 dollars per acre. (See also W94-00972)
